Academic year 2021-22

Solar physics: concepts and quantities

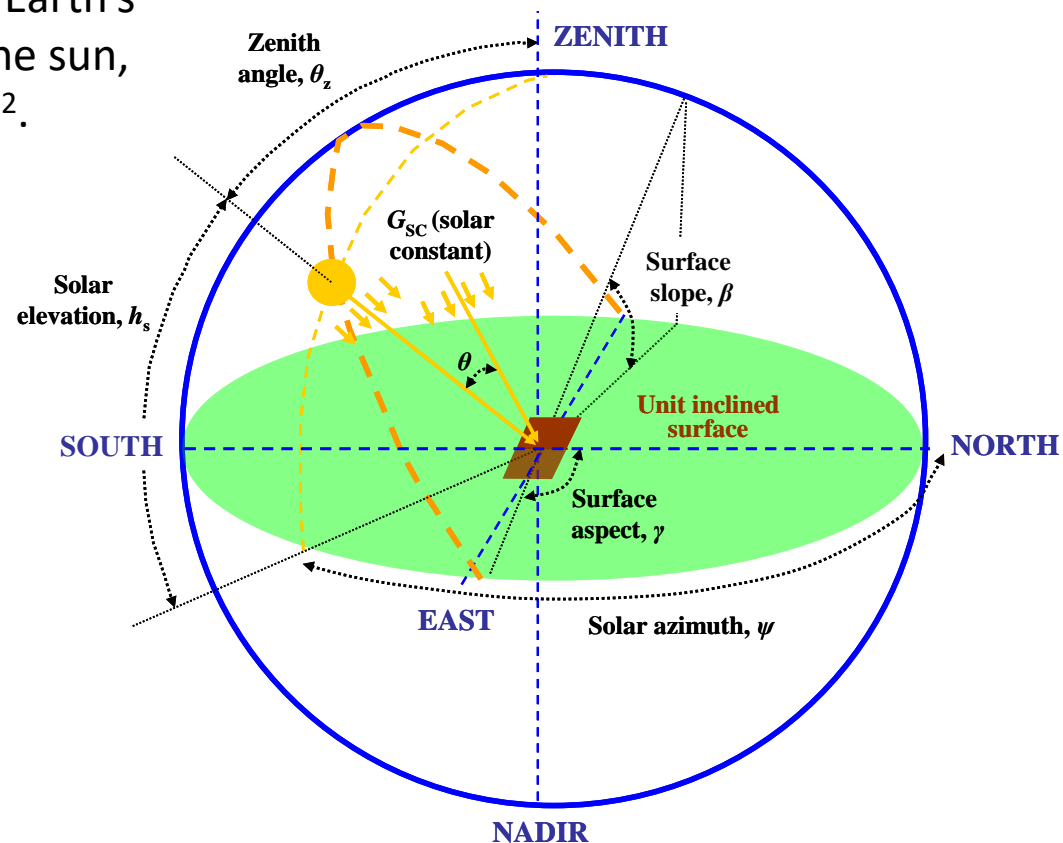

Extraterrestrial radiation: calculations

- The solar radiation received by **the top of the Earth's atmosphere above a horizontal surface** is called the **extraterrestrial (solar) radiation**, R_o , which is expressed in W/m^2 .
- On **daily basis**, the extraterrestrial radiation is estimated by multiplying the solar constant G_{sc} , the eccentricity coefficient d_r , and the zenith angle ϑ_z , i.e.

$$R_a = G_{sc} d_r \cos(\vartheta_z)$$

- The **solar constant** denotes the average density of solar radiation outside the Earth's atmosphere at mean distance from the sun, and is approximately $G_{sc} = 1367 W/m^2$.
- The **eccentricity coefficient** d_r and the **zenith angle** ϑ_z depend on the **solar declination** and the **sunset hour angle**; the former is function of the day of the year, while the latter is also function of the latitude.
- For **hourly or shorter periods**, the solar time angle at the beginning and end of the specific period should be also considered in the calculations.

Extraterrestrial radiation: spatial variability

Since the total area of Earth is $4\pi R^2$, the average solar irradiance in Earth is equal to 25% of the solar constant

The spatial variation of solar radiation depends on the latitude, as the same irradiance affects areas with different sizes

The solar constant (1367 W/m^2) only affects part of the Earth that corresponds to an area of πR^2

With respect to the equator, the area at 45° latitude is 40% larger, it is double at 60° and it is six times larger at 80°

Solar/shortwave/global radiation and its components

- As the radiation penetrates the atmosphere, part of it is **scattered, reflected** or **absorbed** due to the **transmittance of the atmosphere** in the shortwave bands, which depends on the thickness of the atmosphere, the water vapour content, the concentrations of gases, solid particles, etc.
- The **amount of radiation actually reaching a horizontal plane** is known as **solar or shortwave radiation**, R_s . The term “shortwave” derives from the fact that the sun emits energy by means of electromagnetic waves that are characterized by short wavelengths.
- It is also known as **global radiation**, given that it is the sum of:
 - **direct shortwave radiation** from the sun, also referred to as **beam radiation**, R_b
 - **diffuse sky radiation** from all directions, R_d
- The distribution between direct and diffuse radiation depends on the **atmospheric conditions** (humidity, dust, etc.) and the **solar declination**, which is continuous function of time, although, normally, a unique value is considered for every day of the year.
- Under **clear sky conditions**, the diffuse solar radiation is about 15% or more of the total solar radiation received by a horizontal surface, while on **inclined surfaces facing away from the sun**, the proportion of diffuse to total solar radiation may be much higher.
- On a **cloudy day**, the radiation is scattered in the atmosphere, but even under extremely dense cloud cover (when direct radiation tends to zero), about 25% of the extraterrestrial radiation reaches the earth’s surface as diffuse sky radiation.

Solar radiation: measurement & empirical estimations

- The global radiation is measured by **pyranometers, radiometers** or **solarimeters**. These instruments contain a sensor installed on a horizontal surface that measures the intensity of the total solar radiation, i.e., **both direct and diffuse radiation from cloudy conditions**.
- In the absence of measurements, solar radiation is estimated through empirical approaches, such as the Angström formula:

$$R_s = R_a (a_s + b_s n / N)$$

Either provided directly (sunshine values) or in terms of **cloud cover**

where n is the **actual sunshine duration**, N is the **maximum potential daylight hours** (function of **latitude** and **solar declination**), a_s is a regression constant, expressing the fraction of R_a reaching the earth on **overcast days**, when $n = 0$, and $a_s + b_s$ is the fraction of R_a ideally reaching the earth under **clear-sky conditions**, when $n = N$.

- Parameters a_s and b_s depend on the **location**, the **season** and the **state of the atmosphere** and they are related to the distribution of direct and diffuse radiation; if no actual solar radiation data are available for their calibration against local observations, the use of typical values **$a_s = 0.25$ and $b_s = 0.50$** are recommended.

Solar (PV) energy in Greece

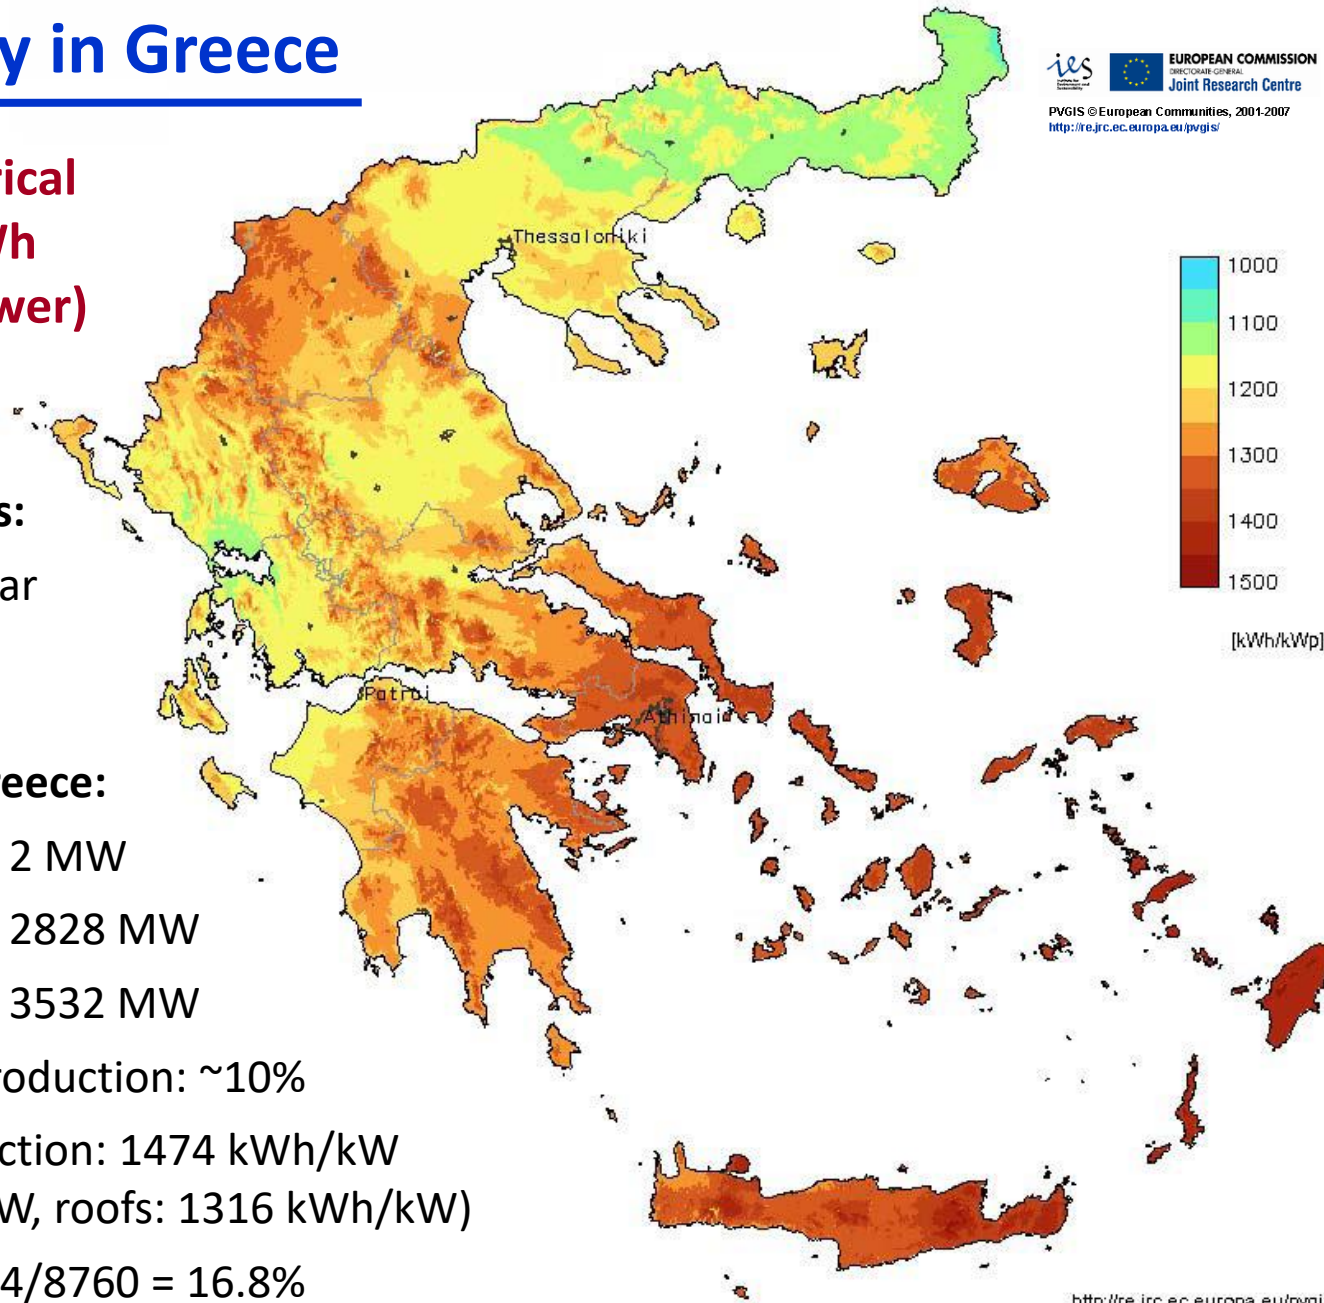

Expected annual electrical energy production (kWh per kW of installed power)

Useful link for fast assessment of PV systems:

<https://selasenergy.gr/solar-calculator-main.php>

Photovoltaic energy in Greece:

- Total capacity 2007: 2 MW
- Total capacity 2019: 2828 MW
- Total capacity 2021: 3532 MW
- Sharing in energy production: ~10%
- Mean annual production: 1474 kWh/kW
(parks: 1500 kWh/kW, roofs: 1316 kWh/kW)
- Capacity factor: $1474/8760 = 16.8\%$

Remarks on PV efficiency (1)

- Efficiency of first commercial panels (1990): 10-11%
- Over last decade, the average panel conversion efficiency has increased from 15% to over 20%, which resulted in the power rating of a standard size panel (156×156 mm) to increase from 250 up to 400 W (Maxeon 3, power capacity 400 W, efficiency 22.6%).
- Solar panel efficiency is determined by:
 - the **photovoltaic cell efficiency**, depending on the cell design and silicon type;
 - the **total panel efficiency**, based on the cell layout, configuration, panel size and the color of protective backsheet (black backsheets absorb more heat).
- The total panel efficiency is measured under **Standard Test Conditions (STC)**, based on a cell temperature of 25°C , solar irradiance of 1000 W/m^2 and air mass of 1.5, for 2.74 hours.
- The effect of deviation from STC (25°C) is accounted for by applying a **power temperature coefficient** ($\%/^{\circ}\text{C}$).
- Typical values: $-0.38\%/^{\circ}\text{C}$ and $-0.40\%/^{\circ}\text{C}$, for mono- and polycrystalline panels.
- Cell temperature is $20\text{-}30^{\circ}\text{C}$ higher than the ambient air temperature, resulting to 8-12% reduction in power output.
- PV efficiency drops significantly with time!

Remarks on PV efficiency (2)

Example panel

- Installed power: 280 W
- Dimensions: 1640 × 990 × 46 mm
- Nominal power achieved at 1000 W/m²

Calculation of efficiency

- Panel area: $1.64 \times 0.99 = 1.624 \text{ m}^2$
- For 1000 W/m² of incoming solar radiation each panel receives 1624 W and produces 280 W of electric power
- Efficiency: $280/1624 = 17.2\%$

- ❑ **Solar module tracking systems** are motorized mechanical racking systems that orient panels so that light strikes perpendicular to the surface of the panels, by tuning the angle at which panels receive solar radiation.
- ❑ Increase of energy output from 20-30%, yet substantially higher **installation and maintenance costs** over static solar plants.
